ABSTRACT
This paper addresses the problem of detection of randomly arriving or departing primary user (PU) signals in cognitive radio systems. The detection problem of the dynamic PU signal is modeled as a binary hypothesis testing problem where the PU signal might randomly depart or arrive during the sensing period. Then, we detect the cyclostationarity of the PU signal using a test statistic derived from the spectral autocorrelation function in dynamic PU signal environments. Numerical results show that the proposed scheme offers an improved spectrum sensing performance than the conventional energy detector for dynamic PU environments.

Keywords: Spectrum sensing, CR, cyclostationarity, dynamic primary user signals.

1. Introduction

The rapid growth of broadband wireless applications makes the frequency spectrum a scarce resource [1], [2], and thus, its more efficient use is needed [3]. The cognitive radio (CR) is a promising technology to exploit underutilized spectrum in an opportunistic manner and the spectrum sensing technique identifying spectrum holes is one of the most important techniques in CR [4]-[6]. Until now, various spectrum sensing techniques have been developed under static traffic circumstances where the spectrum band is assumed to be occupied by the primary user (PU) or vacant during the whole sensing period [7], [8]. In practical cases, however, the PU signal could depart or arrive during the sensing period, especially when a long sensing period is used to achieve a good sensing performance, or when the spectrum sensing is performed for a high traffic network. In dynamic PU signal environments, the performances of the conventional spectrum sensing techniques have been found to be degraded severely [9]. Although a spectrum sensing technique [10] was proposed based on the energy detection approach for dynamic PU signals, it performs poorly when the signal-to-noise ratio (SNR) is low.

In this paper, we propose a novel spectrum sensing scheme based on the cyclostationarity approach for randomly arriving or departing signals, which is referred to as the dynamic PU signals. We first formulate the spectrum sensing problem in dynamic PU signal environments as a binary hypothesis testing problem and develop the corresponding generalized likelihood ratio (GLR). Obtaining an estimate of spectral autocorrelation
function (SAF) of the PU signal and applying it to the GLR, we propose a test statistic for spectrum sensing in dynamic PU signals. The proposed cyclostationarity-based scheme is expected to perform better than the conventional energy detection-based scheme of [10], since the cyclostationarity-based detection has an advantage over the energy detection approach in that its detection performance is generally better than that of the energy detection approach, and also, it can distinguish the PU signal from the interference unlike the energy detection approach.

2. System model

In the conventional researches without considering the dynamic behavior of PU signals, the received signal \( y[n] \) in the absence of noise can be depicted as shown in Figure 1. However, the PU signals can randomly depart or arrive during the sensing period as shown in Figure 2, where the event of random departure (random arrival) is assumed to occur between the samples \( J_0 \) and \( J_0 + 1 \) and \( J_0 + 1 \) for the random departure case, respectively. The goal of the spectrum sensing is to estimate the existence of the PU signal after \( n = N \) by detecting the samples in the sensing period (that is \( n = 1, 2, ..., N \)). For example, in the random departure case, the PU signal is absent after the sensing period meanwhile the PU signal is present after the sensing period in the random arrival case.

We model the spectrum sensing problem in dynamic PU signals where the PU randomly departs or arrives during the sensing period of CR user as a binary hypothesis testing problem: Given the received signal, a decision is to be made between the null hypothesis \( H_0 \) and the alternative hypothesis \( H_1 \) defined as

\[
H_0 : \ y[n] = \begin{cases} 
  x[n] + w[n], \text{ for } n = 1, 2, ..., J_0, \\
  w[n], \text{ for } n = J_0 + 1, J_0 + 2, ..., N
\end{cases}
\]

(1)

and

\[
H_1 : \ y[n] = \begin{cases} 
  w[n], \text{ for } n = 1, 2, ..., J_1, \\
  x[n] + w[n], \text{ for } n = J_1 + 1, J_1 + 2, ..., N
\end{cases}
\]

(2)

respectively, where and represent the sample of the baseband equivalent of the received and PU signals, respectively, \( w[n] \) represents the \( n \)th sample of an additive white Gaussian noise (AWGN) with mean zero and variance \( \sigma^2 \), and \( N \) is the number of samples available during the sensing period. Under the hypothesis \( H_0 \), the random departure of the PU
occurs between the $J_0$th and $(J_0 + 1)$th samples, on the other hand, under the hypothesis $H_a$, the random arrival of the PU occurs between the $J_i$th and $(J_i + 1)$th samples.

3. Proposed scheme

Applying the GLR test to the binary hypothesis model of Eqs. 1 and 2 gives the following decision rule

$$
\rho_\alpha^v(f) = \frac{S_y^v(f)}{[S_y(f + \alpha/2)S_y(f - \alpha/2)]^{1/2}},
$$

where $\alpha$ is a cyclic frequency, $S_y(f)$ is the PSD of $y(t)$, and

$$
S_y^v(f) = \int_{-\infty}^{\infty} R^v_y(\tau)e^{j2\pi f\tau}d\tau,
$$

is the spectral correlation density (SCD) function defined as the Fourier transform of $R^v_y(\tau)$, where $R^v_y(\tau)$ is the cyclic autocorrelation function and expressed as

$$
R^v_y(\tau) = \lim_{A \to \infty} \frac{1}{A} \int_{-A/2}^{A/2} y(t + \tau) \cdot \overline{y(t - \tau)} e^{j2\pi f\tau}dt,
$$

where $\cdot$ is the conjugation operation. From Eqs. 4 and 5, we can see that the SAF is the normalized version of the SCD.

Since $\rho_\alpha^v(f)$ is the SAF of a continuous signal $y(t)$, we cannot replace the discrete value $y^2[n]$ of Eq. 3 with $(\rho_\alpha^v(f))^2$ directly. Thus, we employ the discrete estimate $|\hat{\rho}_\alpha^v(f)|^2$ of the squared magnitude of the SAF obtained as

$$
|\hat{\rho}_\alpha^v(f)|^2 = \frac{\sum_{n=1}^{N} u[n]v'[n]^2}{\sum_{n=1}^{N} |u[n]|^2 \sum_{n=1}^{N} |v[n]|^2}
$$

(7)

to replace $y^2[n]$ of Eq. 3, where $u[n] = y[n]e^{j2\pi f_0(n - 1/2)/T}$ and $v[n] = y[n]e^{j2\pi f_0(n + 1/2)/T}$ are the frequency-shifted versions of $y[n]$. Now, replacing $y^2[n]$ with Eq. 7 yields

$$
\sum_{n=1}^{N} |\hat{\rho}_\alpha^v(f)|^2 - \sum_{n=1}^{N} |\hat{\rho}_\alpha^v(f)|^2 \geq \gamma^v,
$$

(8)

where $\gamma$ is a threshold for the decision rule Eq. 8. It should be noted that the values of $J_0$ and $J_i$ change randomly depending on the behavior of the PU, and thus, the test statistics unconditional for random departure and arrival are obtained by taking the expectation over the left side of Eq. 8 with respect to $J_0$ and $J_i$, respectively. Generally, the number of events occurring randomly over a period of time is well modeled by a Poisson process [12], and thus, we assume that the departure or arrival of the PU follows a Poisson process. Then, we have

$$
Pr\{J_0\} = [1 - e^{-\lambda_0T}] \cdot [e^{-\lambda_0T}]^{\lambda_0},
$$

(9)

and

$$
Pr\{J_i\} = [1 - e^{-\lambda_iT}] \cdot [e^{-\lambda_iT}]^{\lambda_i},
$$

(10)

where $\lambda_0$, $\lambda_i$, and $T$ represent the departure rate, arrival rate, and sampling interval, respectively. Using Eqs. 9 and 10, finally, we obtain the unconditional test statistics

$$
T = \left[ \sum_{J_0=0}^{N-1} [1 - e^{-\lambda_0T}] \cdot [e^{-\lambda_0T}]^{\lambda_0} \sum_{n=J_0}^{N} u[n]v'[n]^2 \right] \left[ \sum_{J_0=0}^{N-1} [1 - e^{-\lambda_iT}] \cdot [e^{-\lambda_iT}]^{\lambda_i} \sum_{n=J_0+1}^{N} |u[n]|^2 \right]^{-1/2}
$$

(11)
Cyclostationarity-based Detection of Randomly Arriving or Departing Signals, Y. Lee et al. / 1083-1091

for the random departure of the PU, and similarly,

\[
T_a = \frac{\sum_{n=1}^{N} [1 - e^{-\lambda_a T_n}] |u[n][v[n]]|}{\sum_{n=1}^{N} [1 - e^{-\lambda_a T_n}] |u[n]|^2 \sum_{n=1}^{N} [1 - e^{-\lambda_a T_n}] |v[n]|^2}
\]  

(12)

for the random arrival of the PU.

From Eqs. 11 and 12, we can see that the term \([1 - e^{-\lambda_a T_n}]\) becomes larger as the value of \(n\) increases, which implies that the cross-correlation \(\sum_{n=1}^{N} [1 - e^{-\lambda_a T_n}] |u[n][v[n]]|\) and the autocorrelations \(\sum_{n=1}^{N} [1 - e^{-\lambda_a T_n}] |u[n]|^2\) and \(\sum_{n=1}^{N} [1 - e^{-\lambda_a T_n}] |v[n]|^2\) are correlation operations that give a larger weight on the samples with a large value of \(n\). Figure 3 shows a block diagram to obtain the test statistic \(T_{sa}\). As \(T_{sa} = T_a\) when \(\lambda_a = \lambda_a\), we can employ either \(T_s\) or \(T_a\) as a test statistic of the proposed scheme assuming that \(\lambda_s = \lambda_s\).

4. Numerical results

In this section, we compare the spectrum sensing performance of the proposed scheme with that of the conventional scheme of [10] in terms of the receiver operating characteristic (ROC) and detection probabilities. We assume the following parameters: \(N = 100\), \(\lambda_s T = 1\), \(\alpha = 2f_c\), \(P_f = 0.01, 0.03, 0.05, 0.15, 0.4,\) and 1, and a PU signal modulated by the binary phase shift keying with a carrier frequency \(f_c\) of 100 Hz. The threshold is determined from the false alarm probabilities [13], and it is assumed that one of the random departure and arrival is chosen randomly with equal probability.

Figure 3. The test statistic \(T_s\) of the proposed scheme.
Figure 4 shows the ROC curves of the proposed and conventional schemes over an AWGN channel in dynamic PU signals with the SNR value of -15, -10, -5, and 0 dB, where $P_d$ represents the detection probability defined as $\Pr(H_1|H_1)$: Here, the SNR is defined as $\sigma_s^2 / \sigma^2$, where $\sigma_s^2$ is the variance of the PU signal. From the figure, it is clearly observed that the proposed scheme provides a significant performance improvement over the conventional scheme, and the performance improvement becomes more noticeable as the SNR increases.

Figure 4. ROC curves of the proposed and conventional schemes over AWGN channel in dynamic PU signals when SNR = -15, -10, -5, and 0 dB.
Figure 5 shows the detection probabilities of the proposed and conventional schemes over AWGN channel in dynamic PU signals as a function of $P_{fa}$ when $P_{fa} = 0.15, 0.05, and 0.01$. From the figure, we can see that the proposed scheme has a better detection performance than the conventional scheme in the SNR range of $-10 \sim 10$ dB. This is due to the fact that cyclostationarity of the signal is easily distinguishable regardless of the SNR value since the AWGN is not a cyclostationary process, whereas it is difficult for the conventional scheme to detect the signal energy correctly in low SNR environments. Moreover, the performance deference between the proposed and conventional schemes becomes more pronounced as the value of the false alarm probability decreases.

Figure 5b. $P_{fa} = 0.05$

![Figure 5c](image3.png)

Figure 5c. $P_{fa} = 0.01$

Figures 6 and 7 show the performances of the proposed and conventional schemes over multipath Rayleigh fading channels in terms of ROC and detection probabilities, respectively. For simulations, we assume that the multipath fading environments consist of three paths with exponential power delay profile (PDP), where the PDP $p_k$ for the $k$th path is expressed as

$$p_k = \frac{\exp(-k\tau)}{\sum_{k=0}^{2} \exp(-k\tau)}$$

and $\tau$ denotes the relative timing difference between the paths [14]. In this paper, we assume that the paths are equally spaced with interval $\tau = N/3$.

Figure 6 shows the ROC curves of the proposed and conventional schemes over multipath Rayleigh fading channels in dynamic PU signal environments with the SNR value of -15, -10, -5, and 0 dB. From the figure, it is clearly observed that the proposed scheme exhibits a better ROC performance than the conventional scheme in multipath Rayleigh fading channels as well. Moreover, the performance improvement over the conventional scheme becomes more significant as the value of SNR increases.

Figure 7 shows the detection probabilities of the proposed and conventional schemes over multipath Rayleigh fading channels in dynamic PU signal environments as a function of SNR when $P_{fa} = 0.15, 0.05, \text{ and } 0.01$. From the figure, we can see that the proposed scheme provides an improved detection performance than the conventional scheme. Moreover, the performance improvement becomes more pronounced as the value of the false alarm probability decreases.

Figure 7. Detection probabilities of the proposed and conventional schemes over multipath Rayleigh fading channels in dynamic PU signals as a function of SNR when $P_{fa} = 0.15$, 0.05, and 0.01.

We also compare the complexities of the proposed and conventional schemes in terms of the number of additions, number of real multiplications, and number of flops, where a flop is defined as a real floating point operation, and a real addition or multiplication is counted as one flop [15]. A complex addition operation is counted as two real addition operations and a complex multiplication operation consists of two real addition and four real multiplication operations.

Table 1 shows the computational complexities of the proposed and conventional schemes. From the table, we can see that the computational complexity of the proposed scheme is almost three times that of the conventional scheme; however, the complexity difference would be insignificant since the recent Intel microprocessor is ideally capable of 4 flops per clock (i.e., a 2.5-GHz Intel microprocessor has a theoretical peak performance of 10 billion flops per second) [16]. Moreover, the complexities of the proposed and conventional schemes are both in order of $N$, which also shows that the spectrum sensing can be achieved in a similar level of sensing time using the both spectrum sensing schemes.

5. Conclusion

In this paper, we have proposed a cyclostationarity-based spectrum sensing scheme in the presence of randomly arriving or departing PU signals. Firstly, we have modeled the spectrum sensing problem in dynamic PU signal environments as a binary hypothesis testing problem, and then, developed the corresponding GLR. Then, we have derived a test statistic employing the SAF in the GLR. From numerical results, it has been demonstrated that the proposed scheme provides a significant performance improvement over the conventional scheme in terms of the ROC and detection probability in both AWGN and multipath Rayleigh fading channels while maintaining a similar level of computational complexity compared with that of the conventional scheme.
